Quality Management of Software and Systems: Model Based Improvement Approaches

- ISO/IEC 9126
- ISO/IEC 12207: 2008 (Basis for process standards)
- EN ISO 9000: series
- CMMI (Successor of CMM)
- ISO/IEC 15504 (SPICE)
- ITIL
- CoBIT
- Personal Software Process (PSP)

- Standard for software quality focusing on **software products** [1].
- It defines software product quality characteristics that can be applied to:
 - Specify functional and non-functional customer and user requirements.
 - Validate the completeness of a requirements definition.
 - Identify software design and testing objectives.
 - Identify quality assurance criteria.
- These characteristics are defined within a *two part quality model*.
- **Software Quality**: describes the degree in which all defined software requirements are fulfilled. There are three different points of view to determine this: user, developer and manager.
- **Quality Model**: describes causal relationships between not tangible views on quality and tangible software measures:
 - Hierarchical ordered quality aspects that in the end lead to software measures.

- Two part quality model: Characteristics for Internal and External Quality:

- **Internal Quality:** describes characteristics of software from an internal point of view. It specifies characteristics of interim (intermediate) products.
- **External Quality:** describes characteristics of software from an external point of view. It is derived from the user's quality requirements.

- Two part quality model: Characteristics for Quality in use:

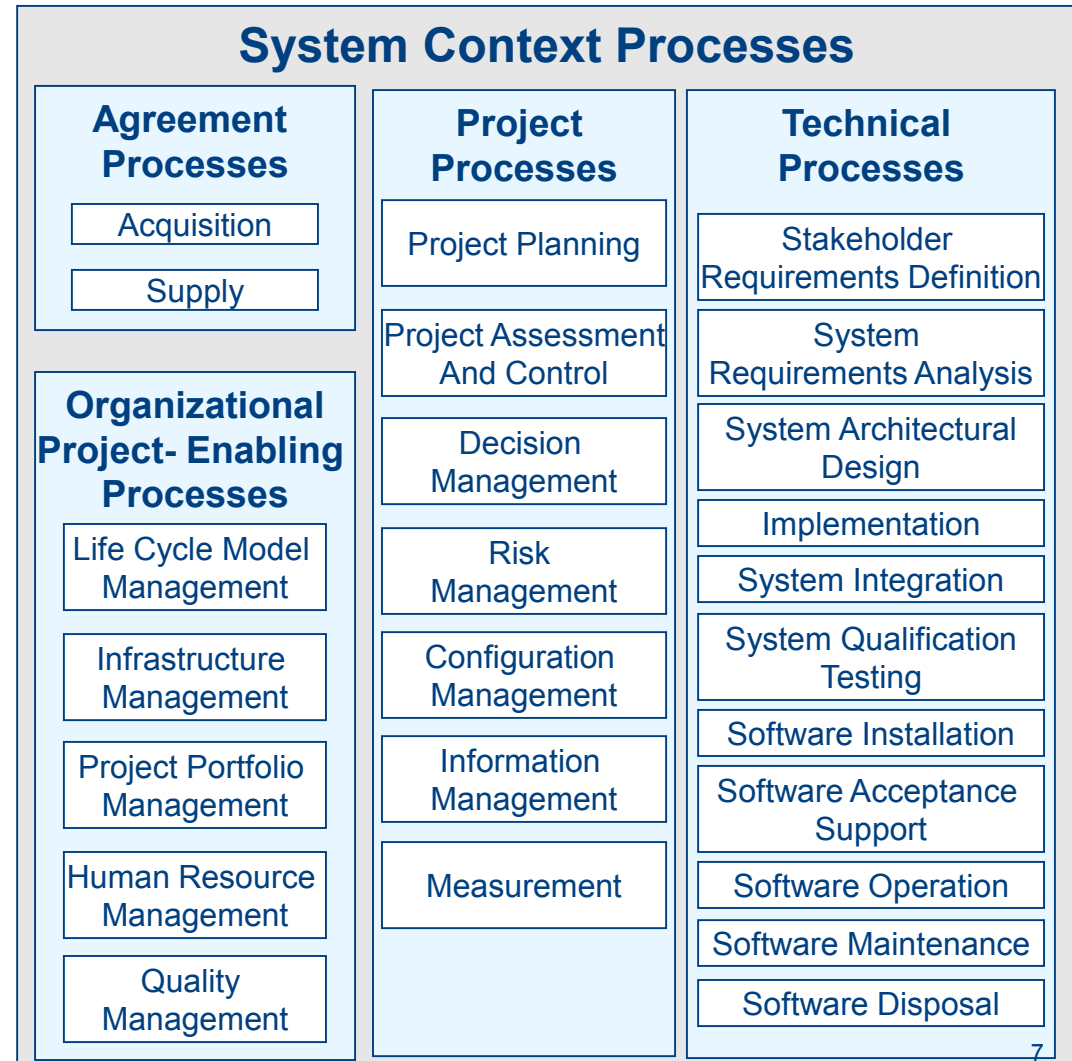

- **Quality in use:** depicts the *user's point of view* with respect to *software quality* in a *specific environment* and a *context of use*.

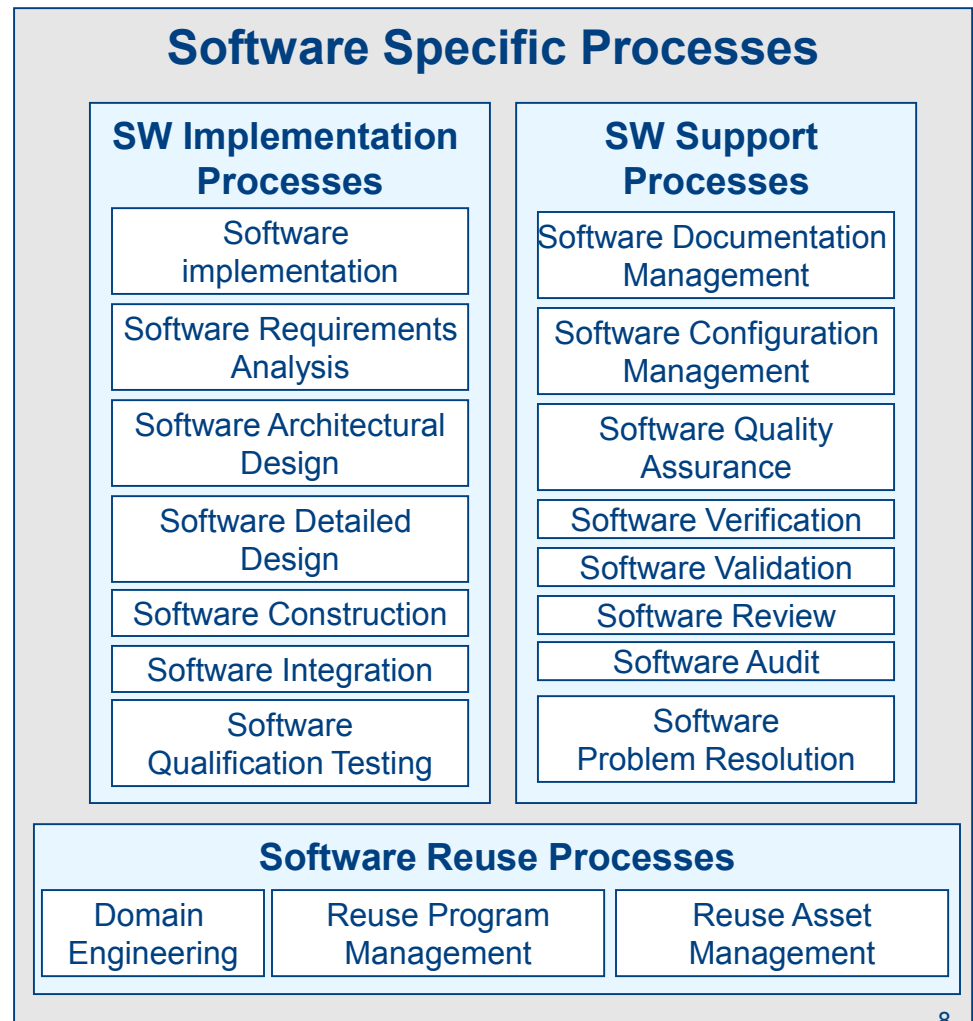

- Provides a common framework for **software life cycle processes** with the purpose of:
 - Providing a standardization of terms to
 - Achieve a common understanding of concepts, thus
 - Facilitating communication among stakeholders in the life cycle of a software product.
- It consists of processes, activities and tasks:
 - 44 processes distributed among 7 process groups.
 - Each process has a defined *purpose* and *outcomes*.
 - Activities and tasks that are required to achieve the expected process *outcomes* are performed.
- It covers the complete software life cycle, starting from its conception until its removal from service.
- It can be performed in combination with the ISO/IEC 15288 standard (System life cycle processes).

- **System context processes** are organized into 4 groups:

- Agreement
- Organizational Project-Enabling
- Project
- Technical

- **Software specific processes** are organized into 3 groups:
 - Implementation
 - Support
 - Reuse

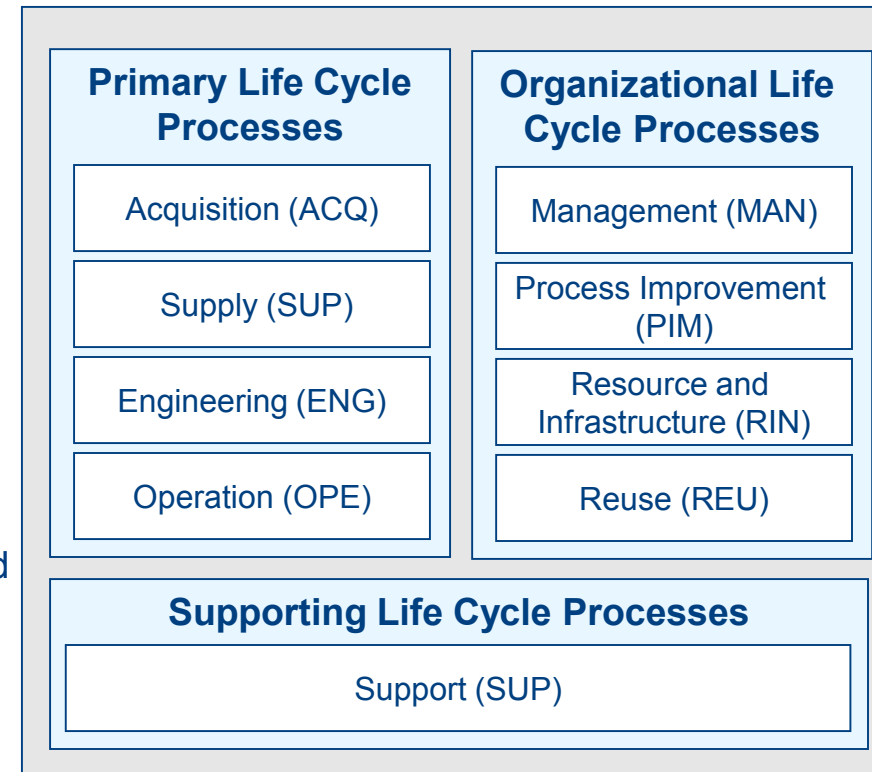

- Series of standards that define fundamentals for quality management systems.
- They represent an international consensus on good quality management practices.
- These standards can be applied within all industrial sectors. In particular, the ISO/IEC 90003:2004 standard is suitable for software.
- Set of standards corresponding to the ISO 9000 series:
 - EN ISO 9000:2005 - Quality management systems - Fundamentals and vocabulary
 - EN ISO 9001:2008 - Quality management systems - Requirements
 - EN ISO 9004:2009 - Managing for the sustained success of an organization - A quality management approach
 - EN ISO 19011:2011 - Guidelines for auditing management systems
 - ISO/IEC 90003:2004 - Software engineering. Guidelines for the application of ISO 9001:2000 to computer software

- A framework for software process improvement [1]. It provides guidelines on how to select strategies toward process improvement, by:
 - Establishing the current level of process maturity in an organization.
 - Identifying drawbacks, which have to be improved in order to achieve a better maturity level.
- The CMM defines 5 maturity levels:
 1. Initial
 2. Repeatable
 3. Defined
 4. Managed
 5. Optimizing
- Each level includes a set of recommended practices in several key areas.
→ It is believed that by performing these practices, an organization will improve its software process capability.

- International standard dedicated to the assessment and improvement of software processes in an organization.
- It consists out of 5 parts:
 - ISO/IEC 15504-1:2004 - Concepts and vocabulary
 - ISO/IEC 15504-2:2003 - Requirements to conduct process assessments
 - ISO/IEC 15504-3:2004 - Support for performing process assessments
 - ISO/IEC 15504-4:2004 - Assistance on use of this standard for process improvement and process capability determination
 - **ISO/IEC 15504-5:2006 – An exemplar process assessment model**
- Analogously to ISO/IEC 12207:1995, this standard defines three process categories within nine different groups.

- **Primary Life Cycle Processes:**
 - ACQ: processes related to software consumers
 - SUP: processes related to software vendors
 - ENG: engineering processes used in software development
 - OPE: processes used for the operation of developed (built) software
- **Organizational Life Cycle Processes**
 - MAN: processes used in project management and related activities.
 - PIM: processes used to improve other processes
 - RIN: processes that supply the infrastructure required by other processes
 - REU: processes applied for the systematic reuse of software components
- **Supporting life cycle processes**
 - SUP: define cross-section processes for the primary life cycle processes e.g. quality assurance processes, and Validation & Verification.

- Assessments are performed by evaluating a chosen subset out of the 49 processes.
- SPICE identifies six capability levels:
 - Level 0: Incomplete
 - Level 1: Performed
 - Level 2: Managed
 - Level 3: Established
 - Level 4: Predictable
 - Level 5: Optimizing
- An assessment is conducted considering predefined *Process Attributes (PA)*, which a process has to fulfill in each of the aforementioned levels.
- For each process, SPICE defines a *Purpose*, its expected *Outcomes* and *Base Practices*.
- Capability grade of a process:
 - Determined by verifying that a process *outcomes* fulfill the *process attributes* of a specific capability level.

- Quasi-standard dedicated to manage the information technology (IT) services.
- Developed in 1989 by the *Office of Government Commerce (OGC)* in Great Britain.
- In particular, ITIL V3 describes a comprehensible IT-service management, which covers the planning, production and support for IT services:
 - Service Strategy
 - Service Design
 - Service Transition
 - Service Operation
 - Service Continual Service Improvement
- Unlike CMM or spice, the focus of ITIL is on production of services and not on systems development!

- **Control Objectives for Information and Related Technology (CoBIT)**, describes a widespread-controlling approach in the area of *IT-Governance*.
- *IT Governance* ensures that the IT-structures and processes of an organization are aligned with its strategies and goals (Business Alignment).
- This approach was first developed by the *Information Systems Audit and Control Association* (ISACA) and then transferred in 2000 to the *IT Governance Institute*.
- Another regulation proposed in the area of IT Governance:
 - Sarbanes-Oxley Act (SOC)

- Motivation: the achievement of higher quality in an organization depends:
 - On the performance of the development group.
 - In turn, the performance of the group depends on the performance delivered by each one of its members.
 - Finally, the performance of each of the development group's members depends on the practices they apply.
- The PSP is an improvement approach focused on the **performance improvement of single software developers**.
- PSP, organized as a self-improvement process (training program), includes a series of exercises that each developer should do (comparable to the CMM levels):
 - PSP0 – Baseline Process
 - PSP1 – Personal Planning Process
 - PSP2 – Personal Quality Management
 - PSP3 – Cyclic Personal Process
