## Software Quality Assurance (WS 10/11)

Problem Set 7 Due Wednesday, February 9<sup>th</sup>, 2011

## **Problem 1: Data Flow Anomaly Analysis**

Consider the following Java implementation of the class Switch. The class is a module of a technical application which is classified as safety-critical.

A switch provides a return value which depends on the internal state and the given input value. The return value is true if input and internal state coincide, else it is false. Every usage modifies the internal state of the switch.

a) Judge whether the class Switch complies with the given requirements.

b) Perform a data flow anomaly analysis for the operation toggle.

## **Problem 2: Data Flow Anomaly Analysis**

A software company develops software packages for commercial animal housing. A particular function, which is implemented in the C programming language, computes the daily amount of feed for different animal species depending on their individual weight.

Until now, this function was only part of a software package for farms and worked failurefree since years. Recently, it is also included in a software package for zoological gardens and it produces wrong output in some cases. By performing a data flow analysis, the faults should be revealed.

```
/* Own data type for enumeration of animal species */
typedef enum {COW, HORSE, PIG, ELEPHANT} Animal A;
/* Function for determining the daily amount of feed depending
 * on the animal species and the individual weight
*/
01 float feedamount(Animal A species, float weight)
02 {
     float amount, factor;
03
04
     switch (species)
05
     {
       case COW:
06
07
       {
         factor = 0.05;
08
09
         break;
10
       }
       case HORSE:
11
12
       {
13
         factor = 0.1;
14
         break;
15
       }
       case PIG:
16
17
       {
18
         factor = 0.02;
19
         break;
20
       }
21
     } // end switch
22
     amount = factor * weight;
23
     return amount;
24 } // end feedamount
```

a) What mistakes were performed and how would the consequences have been avoided?

b) Perform a data flow anomaly analysis for the operation feedamount.

## **Problem 3: Data Flow Anomaly Analysis**

Consider the following Java implementation of the operation ALL\_POSITIVE which checks whether all elements of a one-dimensional array are positive. As parameters, the field and its length are given.

```
01 boolean ALL_POSITIVE(int[] array, int len) {
02
     boolean result;
03
     int i,tmp;
04
     i=0;
05
     result=true;
     while (i<len&&result) {</pre>
06
07
       tmp=array[i];
       if (tmp<=0)</pre>
08
          result=false;
09
10
       i++;
11
     }
     return result;
12
13 }
```

Perform a data flow anomaly analysis for the operation ALL\_POSITIVE.
